

Spread Operator

The spread operator (...) is used to unpack elements of an array or object. It allows easy copying, merging, or passing array values as separate arguments.

Rest Parameter

The rest parameter (...) is used in function definitions to collect all remaining arguments into an array. It allows a function to accept an indefinite number of arguments.

How to convert strings to numbers

In JavaScript, numbers are sometimes stored as strings, which makes them unusable in calculations. To fix this, we need to convert the string into a number. Here are the main ways to do it:

Number() → Converts a string into a number (works with integers and decimals).

parseInt() → Converts a string into an integer, ignoring decimals.
